## Entities

| Entity  | Description                                         |
|---------|-----------------------------------------------------|
| STUDENT | The person registering for an event.                |
| EVENT   | A campus event open for registration.               |
| BOOKING | A single student's registration for a single event. |

## Relationships

| Relationship       | Cardinality | Meaning                              |
|--------------------|-------------|--------------------------------------|
| STUDENT -> BOOKING | 1 : N       | One student may make many bookings.  |
| EVENT -> BOOKING   | 1 : N       | One event may receive many bookings. |

BOOKING is an associative entity that resolves the many-to-many relationship between STUDENT and EVENT: a student may register for many events, and an event may be booked by many students.

## Notation

|    |                                                                |
|----|----------------------------------------------------------------|
| PK | Primary Key - uniquely identifies a row.                       |
| FK | Foreign Key - references another entity's primary key.         |
| {  | Crow's-foot symbol at the BOOKING end denotes the 'many' side. |

## Implementation Note

In this demo, data is stored in the browser using localStorage rather than a relational database. As a result, the student attributes are kept inside the booking object rather than in a separate table. The conceptual model shown above represents the schema a database-backed version of this project would use.
